

## Solution Problem 2

a) We consider argon an ideal mono-atomic gas and the collisions of the atoms with the piston perfect elastic. In such a collision with a fix wall the speed  $\vec{v}$  of the particle changes only the direction so that the speed  $\vec{v}$  and the speed  $\vec{v}'$  after collision there are in the same plane with the normal and the incident and reflection angle are equal.

$$v_n' = -v_n, \quad v_t' = v_t \quad (1)$$

In the problem the wall moves with the speed  $\vec{u}$  perpendicular on the wall. The relative speed of the particle with respect the wall is  $\vec{v} - \vec{u}$ . Choosing the Oz axis perpendicular on the wall in the sense of  $\vec{u}$ , the conditions of the elastic collision give:

$$\begin{aligned} (\vec{v} - \vec{u})_z &= -(\vec{v}' - \vec{u})_z, \quad (\vec{v} - \vec{u})_{x,y} = (\vec{v}' - \vec{u})_{x,y}; \\ v_z - u &= -\left(v_z' - u\right), \quad v_z' = 2u - v_z, \quad v_{x,y}' = v_{x,y} \end{aligned} \quad (2)$$

The increase of the kinetic energy of the particle with mass  $m_o$  after collision is:

$$\frac{1}{2}m_o v'^2 - \frac{1}{2}m_o v^2 = \frac{1}{2}m_o (v_z'^2 - v_z^2) = 2m_o u(u - v_z) \approx -2m_o u v_z \quad (3)$$

because  $u$  is much smaller than  $v_z$ .

If  $n_k$  is the number of molecules from unit volume with the speed component  $v_{zk}$ , then the number of molecules with this component which collide in the time  $dt$  at the area  $dS$  of the piston is:

$$\frac{1}{2}n_k v_{zk} dt dS \quad (4)$$

These molecules will have a change of the kinetic energy:

$$\frac{1}{2}n_k v_{zk} dt dS (-2m_o u v_{zk}) = -m_o n_k v_{zk}^2 dV \quad (5)$$

where  $dV = u dt dS$  is the increase of the volume of gas.

The change of the kinetic energy of the gas corresponding to the increase of volume  $dV$  is:

$$dE_c = -m_o dV \sum_k n_k v_{zk}^2 = -\frac{1}{3} n m_o \bar{v}^2 dV \quad (6)$$

and:

$$dU = -\frac{2}{3} N \frac{m_o \bar{v}^2}{2} \cdot \frac{dV}{V} = -\frac{2}{3} U \frac{dV}{V} \quad (7)$$

Integrating equation (7) results:

$$U V^{2/3} = \text{const.} \quad (8)$$

The internal energy of the ideal mono-atomic gas is proportional with the absolute temperature  $T$  and the equation (8) can be written:

$$T V^{2/3} = \text{const.} \quad (9)$$

b) The oxygen is in contact with a thermostat and will suffer an isothermal process. The internal energy will be modified only by the adiabatic process suffered by argon gas:

$$\Delta U = \nu C_V \Delta T = m c_V \Delta T \quad (10)$$

where  $\nu$  is the number of kilomoles. For argon  $C_V = \frac{3}{2}R$ .

For the entire system  $L=0$  and  $\Delta U = Q$ .

We will use indices 1, respectively 2, for the measures corresponding to argon from cylinder A, respectively oxygen from the cylinder B:

$$\Delta U = \frac{m_1}{\mu_1} \cdot \frac{3}{2} \cdot R(T' - T_1) = Q = \frac{m_1}{\mu_1} \cdot \frac{3}{2} RT_1 \left[ \left( \frac{V_1}{V'} \right)^{2/3} - 1 \right] \quad (11)$$

From equation (11) results:

$$T_1 = \frac{2}{3} \cdot \frac{\mu_1}{m_1} \cdot \frac{Q}{R} \cdot \frac{1}{\left( \frac{V_1}{V'} \right)^{2/3} - 1} = 1000K \quad (12)$$

$$T' = \frac{T_1}{4} = 250K \quad (13)$$

For the isothermal process suffered by oxygen:

$$\frac{\rho'_2}{\rho_2} = \frac{p'_2}{p_2} \quad (14)$$

$$p'_2 = 2,00 \text{ atm} = 2,026 \cdot 10^5 \text{ N/m}^2$$

From the equilibrium condition:

$$p'_1 = p'_2 = 2 \text{ atm} \quad (15)$$

For argon:

$$p_1 = p'_1 \cdot \frac{V'_1}{V_1} \cdot \frac{T_1}{T'} = 64 \text{ atm} = 64,9 \cdot 10^5 \text{ N/m}^2 \quad (16)$$

$$V_1 = \frac{m_1}{\mu_1} \cdot \frac{RT_1}{p_1} = 1,02 \text{ m}^3, V'_1 = 8V_1 = 8,16 \text{ m}^3 \quad (17)$$

c) When the valve is opened the gases intermix and at thermal equilibrium the final pressure will be  $p'$  and the temperature  $T$ . The total number of kilomoles is constant:

$$\nu_1 + \nu_2 = \nu', \frac{p'_1 V'_1}{RT'_1} + \frac{p'_2 V'_2}{RT} = \frac{p(V'_1 + V'_2)}{RT} \quad (18)$$

$$p'_1 + p'_2 = 2 \text{ atm}, T_2 = T' = T = 300K$$

The total volume of the system is constant:

$$V_1 + V_2 = V'_1 + V'_2, \quad \frac{V'_2}{V_2} = \frac{\rho_2}{\rho'_2}, \quad V'_2 = \frac{V_2}{2} = 7,14 \text{ m}^3 \quad (19)$$

From equation (18) results the final pressure:

$$p = p'_1 \cdot \frac{1}{V_1 + V_2} \cdot \left( V'_1 \cdot \frac{T}{T'_1} + V'_2 \right) = 2,2 \text{ atm} = 2,23 \cdot 10^5 \text{ N/m}^2 \quad (20)$$
